Mount Everest

From Wikipedia, the free encyclopedia

Coordinates: 27°59'17"N 86°55'31"E

"Everest" redirects here. For other uses, see [Everest \(disambiguation\)](#).

This article's tone or style may not reflect the [encyclopedic tone used on Wikipedia](#). See Wikipedia's [guide to writing better articles](#) for suggestions. (October 2017) ([Learn how and when to remove this template message](#))

Mount Everest, known in Nepali as Sagarmāthā and in Tibetan as Chomolungma, is Earth's highest mountain above sea level, located in the Mahalangur Himal sub-range of the Himalayas. The international border between China (Tibet Autonomous Region) and Nepal (Province No. 1) runs across its summit point.

The current official elevation of 8,848 m (29,029 ft), recognised by China and Nepal, was established by a 1955 Indian survey and subsequently confirmed by a Chinese survey in 1975.^[1] In 2005, China remeasured the rock height of the mountain, with a result of 8844.43 m. There followed an argument between China and Nepal as to whether the official height should be the rock height (8,844 m., China) or the snow height (8,848 m., Nepal). In 2010, an agreement was reached by both sides that the height of Everest is 8,848 m, and Nepal recognises China's claim that the rock height of Everest is 8,844 m.^[5]

In 1865, Everest was given its official English name by the Royal Geographical Society, upon a recommendation by Andrew Waugh, the British Surveyor General of India. As there appeared to be several different local names, Waugh chose to name the mountain after his predecessor in the post, Sir George Everest, despite George Everest's objections.^[6]

Mount Everest attracts many climbers, some of them highly experienced mountaineers. There are two main climbing routes, one approaching the summit from the southeast in Nepal (known as the "standard route") and

Intuition of distributional word similarity

- Nida (1975) example:

A bottle of **tesgüino** is on the table
Everybody likes **tesgüino**
Tesgüino makes you drunk
We make **tesgüino** out of corn.

- From context words humans can guess **tesgüino** means *an alcoholic beverage like beer*
- Intuition for algorithm:
Two words are similar if they have similar word contexts.

Distributional Hypothesis

If we consider **optometrist** and **eye-doctor** we find that, as our corpus of utterances grows, these two occur in almost the same environments. In contrast, there are many sentence environments in which **optometrist** occurs but **lawyer** does not...

It is a question of the relative frequency of such environments, and of what we will obtain if we ask an informant to substitute any word he wishes for **oculist** (not asking what words have the same meaning).

These and similar tests all measure the probability of particular environments occurring with particular elements... If A and B have almost identical environments we say that they are synonyms.

—Zellig Harris (1954)

Information Retrieval

- Vector Space Models were initially developed in the SMART information retrieval system (Salton, 1971)
- Each document in a collection is represented as point in a space (a vector in a vector space)
- A user's query is a pseudo-document and is represented as a point in the same space as the documents
- Perform IR by retrieving documents whose vectors are close together in this space to the query vector

What does comparing two row vectors do?

Vector comparisons

	doc_X	doc_Y
A	2	4
B	10	15
C	14	10

Vector comparisons

	doc _x	doc _y
A	2	4
B	10	15
C	14	10

**doc_y is a positive movie review
doc_x is a less positive movie review**

**A = "superb" positive / low frequency
B = "good" positive / high frequency
C = "disappointing" negative / high frequency**

Vector comparisons

	doc _X	doc _Y
A	2	4
B	10	15
C	14	10

Vector comparisons

	docx	docy
A	2	4
B	10	15
C	14	10

Euclidean distance : vectors u, v of dimension N

$$\sqrt{\sum_{i=1}^N |u_i - v_i|^2}$$

Vector comparisons

	docx	docy
A	2	4
B	10	15
C	14	10

Euclidean distance : vectors u, v of dimension N

$$\sqrt{\sum_{i=1}^N |u_i - v_i|^2}$$

Vector L2 (length) Normalization

	doc_X	doc_Y	 u
A	2	4	4.47
B	10	15	18.02
C	14	10	17.20

$$\|u\| = \sqrt{\sum_{i=1}^n u_i^2}$$

Vector L2 (length) Normalization

	doc _X	doc _Y	u
A	2/4.47	4/4.47	4.47
B	10/18.02	15/18.02	18.02
C	14/17.2	10/17.2	17.20

$$\|u\| = \sqrt{\sum_{i=1}^n u_i^2}$$

Divide each vector by its L2 length

Vector L2 (length) Normalization

	doc _X	doc _Y
A	0.45	0.89
B	0.55	0.83
C	0.81	0.58

Now Good is
closer to Superb
than to Disappointing

Cosine Distance

$$1 - \frac{\sum_{i=1}^n u_i \times v_i}{\sqrt{\sum_{i=1}^n u_i^2} \times \sqrt{\sum_{i=1}^n v_i^2}}$$

Cosine does the L₂ normalization too

Cosine angle between vectors tells us their similarity

Term-Term Matrix

Context windows

w-2, w-1 **target_word** w+1 w+2

The government must not **abdicate** responsibility to non-elected
it has led men to **abdicate** their family responsibilities
other demands, but declining to **abdicate** his responsibility
leaders **abdicate** their role and present people with no plans

	his	leaders	not	responsibility	to
abandon	1	1	1	2	3

Context windows

- Occur in a window of +/- 2 words, in the same sentence, in the same document
- Instead of window of words use more complex contexts: dependency patterns. Subj-of-verb, adj-mod, obj-of-verb
- Languages have long distance dependencies

*The **pictures are** beautiful.*

*The **pictures** of the old man **are** beautiful.*

*The **pictures** of the old man holding his grandchild **are** beautiful.*

Using syntax to define a word's context

- Zellig Harris (1968) “The meaning of entities, and the meaning of grammatical relations among them, is related to the restriction of combinations of these entities relative to other entities”
- **Duty** and **Responsibility** have similar syntactic distributions

Modified by adjectives	additional, administrative, assumed, collective, congressional, constitutional ...
Object of verbs	assert, assign, assume, attend to, avoid, become, breach..

Alternates to counts

- Raw word frequency is not a great measure of association between words. It's very skewed “the” and “of” are very frequent, but maybe not the most discriminative
- We'd rather have a measure that asks whether a context word is particularly informative about the target word.
- Instead of raw counts, it's common to transform vectors using TF-IDF or PPMI

TF-IDF

*Term frequency * inverse document frequency*

How often a word occurred in a document

1 over the number of documents that it occurred in

Sparse v. Dense Vectors

- Co-occurrence matrix (weighted by TF-IDF or mutual information)
- **Long** ($\text{length } |\mathcal{V}| = 50,000+$)
- **Sparse** (most elements are zeros)
- Alternative: learn vectors that are
 - **Short** ($\text{length } 200\text{-}1000$)
 - **Dense** (most elements are non-zero)

Sparse v. Dense Vectors

- Why dense vectors? Short vectors may be easier to use as features in machine learning (fewer weights to tune)
- Dense vectors may *generalize* better than storing explicit counts
- Neural networks produce dense vectors as output from their final hidden layer. These "word embeddings" are very popular at the moment

Skip-grams, CBOW

Mikolov et al. 2013

Learn embeddings as part of the process of word prediction.

Train a neural network to predict neighboring words

Inspired by neural net language models.

In so doing, learn dense embeddings for the words in the training corpus.

Advantages:

Fast, easy to train (much faster than SVD)

Available online in the word2vec package

Including sets of pretrained embeddings!

Skip-Grams

- Predict each neighboring word in a context window of $2C$ of surrounding words
- So for $C=2$, we are given a word w_t and we try to predict its 4 surrounding words
- $[w_{t-2}, w_{t-1}, w_{t+1}, w_{t+2}]$
- Uses "negative sampling" for training

Negative sampling

lemon, a [tablespoon of apricot preserves or] jam

Abstract

Vector space embedding models like word2vec, GloVe, and fastText are extremely popular representations in natural language processing (NLP) applications. We present Magnitude, a fast, lightweight tool for utilizing and processing embeddings. Magnitude is an open source Python package with a compact vector storage file format that allows for efficient manipulation of huge numbers of embeddings. Magnitude performs common operations up to 60 to 6,000 times faster than Gensim. Magnitude introduces several novel features for improved robustness like

Metric	Cold	Warm
Initial load time	97x	—
Single key query	1x	110x
Multiple key query (n=25)	68x	3x
k-NN search query (k=10)	1x	5,935x

Table 1: Speed comparison of Magnitude versus Gensim for common operations. The ‘cold’ column represents the first time the operation is called. The ‘warm’ column indicates a subsequent call with the same keys.

file, a 97x speed-up. Gensim uses 5GB of RAM versus 18KB for Magnitude.

Demo of word vectors

```
# Install Magnitude  
pip3 install pymagnitude
```

```
# Download Google's word2vec vectors  
wget http://magnitude.plasticity.ai/word2vec+approx/GoogleNews-vectors-negative300.magnitude  
# Warning it's 11GB large
```

```
# Start Python, and try the commands  
# on the next slide  
python3
```

Demo of word vectors

```
from pymagnitude import *
vectors = Magnitude("GoogleNews-vectors-
negative300-2.magnitude")

queen = vectors.query('queen')
king = vectors.query("king")
vectors.similarity(king, queen)
# 0.6510958

vectors.most_similar_approx(king, topn=5)
#[('king', 1.0), ('kings', 0.72),
('prince', 0.62), ('sultan', 0.59),
('ruler', 0.58)]
```

Does similarity == semantics?

- Word vectors fail to capture logical implications

$\text{Dog}(x) \rightarrow \text{Animal}(x)$

$\text{Dog}(x) \rightarrow \text{not } (\text{Gorilla}(x))$

- Word vectors for antonyms or logically exclusive things are often very similar

$\text{sim}(\text{boys}, \text{girls})$

$\text{sim}(\text{cats}, \text{dogs})$

$\text{sim}(\text{France}, \text{Germany})$

$\text{sim}(\text{rise}, \text{fall})$
